Converting to Pasture or Hay—
Evaluating Current Vegetation

How good is your CRP land after 10 or more years of non-use? Some CRP fields were established hurriedly with minimal cost and effort. Some were sown with second or third choice seed mixtures due to seed shortages in the early years of the CRP period. For these reasons and others, many CRP fields have thin grass sods, undesired grass species, or weeds and brush present. Fortunately, some have developed into dense, weed-free stands of the species that were planted.

Don't make a hasty decision and destroy your current CRP vegetation until you have seriously evaluated what you now have. In some cases it will be adequate, as is, to begin grazing or harvesting for hay or may need only minor improvements or management steps to upgrade it to an acceptable condition. In some situations however, major changes or renovation will be necessary before the site can be used successfully in a forage/livestock enterprise. Use table 1 to help you evaluate the adequacy of vegetation on your CRP site. It offers alternatives if improvements are needed.

Table 1 shows some forage management practices that can improve the productivity or quality of the existing types of forage (remove weeds or include legumes). Various seeding and renovation methods allow you to add more desirable grasses and legumes to what you already have. Examples follow.

- Rather than a broadcast herbicide treatment which might harm legumes, use clipping and “spot treating” with herbicide for weed or brush control where desirable legumes exist.

- Use phosphorus and potassium with no or only low rates of nitrogen on grass/legume stands to keep the grasses less competitive and to favor the maintenance of the legumes.

- Use moderate to high rates of nitrogen on all-grass stands to stimulate grass production and improve vigor and stand density.

- Where grass stands are thin and you wish to include more grass or legumes, use interseeding (no-till, sod seeding) or “frost seeding” to introduce the legume component without destroying the existing grass.

- Where grass that is present is not necessarily the desired grass, complete renovation either with tillage or by no-till means may be the best and quickest way to return to a desired forage production condition.

*legume

+Frost seeding and interseeding of legumes frequently are not successful when grass sod is dense, particularly when nitrogen is being used to further stimulate grass growth.
